Scanner Class in Java

Last Updated : 04 Jan, 2025

In Java, Scanner is a class in java.util package used for obtaining the input of the primitive types like int, double, etc. and strings.

Using the Scanner class in Java is the easiest way to read input in a Java program, though not very efficient if you want an input method for scenarios where time is a constraint like in competitive programming.

Java Scanner Input Types

Scanner class helps to take the standard input stream in Java. So, we need some methods to extract data from the stream. Methods used for extracting data are mentioned below:

Method	Description
<u>nextBoolean()</u>	Used for reading Boolean value
<u>nextByte()</u>	Used for reading Byte value
<u>nextDouble()</u>	Used for reading Double value
<u>nextFloat()</u>	Used for reading Float value
<u>nextInt()</u>	Used for reading Int value

Method	Description
<u>nextLine()</u>	Used for reading Line value
<u>nextLong()</u>	Used for reading Long value
<u>nextShort()</u>	Used for reading Short value

Let us look at the code snippet to read data of various data types.

Examples of Java Scanner Class

Example 1:

```
// Java program to read data of various types
// using Scanner class.
import java.util.Scanner;

// Driver Class
public class ScannerDemo1 {
    // main function
    public static void main(String[] args)
    {
        // Declare the object and initialize with
        // predefined standard input object
        Scanner sc = new Scanner(System.in);

        // String input
        String name = sc.nextLine();

        // Character input
        char gender = sc.next().charAt(0);

        // Numerical data input
        // byte, short and float can be read
        // using similar-named functions.
        int age = sc.nextInt();
        long mobileNo = sc.nextLong();
        double cgpa = sc.nextDouble();

        // Print the values to check if the input was
        // correctly obtained.
        System.out.println("Name: " + name);
        System.out.println("Gender: " + gender);
        System.out.println("Age: " + age);
        System.out.println("Mobile Number: " + mobileNo);
        System.out.println("CGPA: " + cgpa);
    }
}
```

```
}  
}
```

Input

```
Geek  
F  
40  
9876543210  
9.9
```

Output

```
Name: Geek  
Gender: F  
Age: 40  
Mobile Number: 9876543210  
CGPA: 9.9
```

Sometimes, we have to check if the next value we read is of a certain type or if the input has ended (EOF marker encountered).

Then, we check if the scanner's input is of the type we want with the help of hasNextXYZ() functions where XYZ is the type we are interested in. The function returns true if the scanner has a token of that type, otherwise false. For example, in the below code, we have used hasNextInt(). To check for a string, we use hasNextLine(). Similarly, to check for a single character, we use hasNext().charAt(0).

Example 2:

Let us look at the code snippet to read some numbers from the console and print their mean.

```
// Java program to read some values using Scanner  
// class and print their mean.  
import java.util.Scanner;  
  
public class ScannerDemo2 {  
    public static void main(String[] args)  
    {  
        // Declare an object and initialize with  
        // predefined standard input object
```

```
Scanner sc = new Scanner(System.in);

// Initialize sum and count of input elements
int sum = 0, count = 0;

// Check if an int value is available
while (sc.hasNextInt()) {
    // Read an int value
    int num = sc.nextInt();
    sum += num;
    count++;
}
if (count > 0) {
    int mean = sum / count;
    System.out.println("Mean: " + mean);
}
else {
    System.out.println(
        "No integers were input. Mean cannot be calculated.");
}
}
```

Input

1 2 3 4 5

Output

Mean: 3

Important Points About Java Scanner Class

- To create an object of Scanner class, we usually pass the predefined object System.in, which represents the standard input stream. We may pass an object of class File if we want to read input from a file.
- To read numerical values of a certain data type XYZ, the function to use is nextXYZ(). For example, to read a value of type short, we can use nextShort()
- To read strings, we use nextLine().
- To read a single character, we use next().charAt(0). next() function returns the next token/word in the input as a string and charAt(0) function returns the first character in that string.
- The Scanner class reads an entire line and divides the line into tokens. Tokens are small elements that have some meaning to the

Java compiler. For example, Suppose there is an input string: How are you

In this case, the scanner object will read the entire line and divides the string into tokens: “How”, “are” and “you”. The object then iterates over each token and reads each token using its different methods.
